## Establishing Environmental Data for Monitoring Foliar Diseases in a Nursery Setting

## Dr. J.T. Walker

Plant diseases are common occurrences in nurseries and considerable effort is devoted to minimizing their effects by different management practices. Since most of the diseases are caused by fungi and these fungi may produce tremendous numbers of spores (conidia) which germinate and penetrate susceptible plant parts under moist conditions, it was the objective of this project to determine how long water or moisture may be present in a nursery environment, and eventually to monitor the presence of leaf spot disease on susceptible plants and relate this information to the number of hours wetness that occur during a growing season.

At the Center for Applied Nursery Research two meteorological monitoring systems were installed with leaf wetness sensors. One of the systems, when operating, provides air temperature, evapo-transportation, solar radiation, barometric pressure, wind speed and wind direction, relative humidity and precipitation information at pre-set intervals. The other system is a backup for the leaf wetness sensor. Wiring from the weather station shelters to a computer in the Center's building allows for storage, summation, and retrieval of data. Phone modems eventually will permit transmission of this information to off-site locations.

An example of the information obtained from one system is provided for August 30, 1997. The irrigations system, set for 6:30 am, completely wet the leaves for  $2\frac{1}{2}$  hours and partially wet them for an additional hour. If temperatures were optimum for a particular fungal spore to germinate, it may have produced a germ tube and invaded a susceptible leaf in that period. A brief afternoon shower (1:30 pm) wet the leaves but apparently became dry after one hour.

Weather information from our National Weather Service is important for many activities including agricultural practices. However, in order to understand the effect of micro environmental on disease development the data must be obtained where the plants are growing. In any facet of growing plants, the more we can learn about the impact of different environments the better management can plan, produce and market their products economically.
